Abstract: The researchers have established that 4-5% of population have problems with attention deficit and hyperactivity. The symptoms already occur in early childhood which become more accentuated when children enter school. These children's school achievement is low, due to this depression, aggression and anxiety may also appear. This research investigates the possibility of cognitive development of children with attention deficit and hyperactivity. In the research were included 8 children with ADHD who were involved in a cognitive development program. The aim was to develop these children's analytical-synthesizer ability, the memory and the problem solving skills. The results show that the intervention I used had positive effects on analytical-synthesizer ability but it didn't influence the memory and the problem solving skills.

Keywords: attention deficit, hyperactivity, development of children with ADHD
