Abstract: The study examines the possibilities of alternation the spatial dimension in imaginary tasks, within which the gradual structural construction makes possible to shift the two-dimensional interpretation to a three-dimensional one. One-third of the people are able to do this, whereas the rest are able to complete the task only after having drawn the mental image.

This ability does not show any relationship to sex, age or the used spatial frame of reference, however it is significant in the aspect of years of study, and it indicates that tacit knowledge cannot be avoided in any interpretation.

Keywords: mental image, spatial dimension, tacit knowledge
